Factor 1 [41%]

Factor 3 [19%]

Agenda

- Factor analysis
- Canonical Correlation Analysis (CCA)
 - what can it be used for

The Factor Model

$$[X_1 \quad \cdots \quad X_n] = A[F_1 \quad \cdots \quad F_n] + [G_1 \quad \cdots \quad G_n]$$

$$\mathbf{X} = \mathbf{A}\mathbf{F} + \mathbf{G}$$

$$\begin{bmatrix} X_1 \\ \vdots \\ X_k \end{bmatrix} = \begin{bmatrix} a_{11} & \cdots & a_{1m} \\ \vdots & & \vdots \\ a_{k1} & \cdots & a_{km} \end{bmatrix} \begin{bmatrix} F_1 \\ \vdots \\ F_m \end{bmatrix} + \begin{bmatrix} G_1 \\ \vdots \\ G_k \end{bmatrix}$$

$$V(\mathbf{X}) = \mathbf{R} = \begin{bmatrix} 1 & \cdots & \rho_{1k} \\ \vdots & \ddots & \vdots \\ \rho_{k1} & \cdots & 1 \end{bmatrix}$$

$$V(\mathbf{F}) = \mathbf{I} = \mathbf{I}_m = \begin{bmatrix} 1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & 1 \end{bmatrix}$$

$$V(\mathbf{G}) = \mathbf{\Delta} = \begin{bmatrix} \delta_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \delta_k \end{bmatrix}$$

$$\text{Cov}(\mathbf{F}, \mathbf{G}) = \mathbf{0} = \begin{bmatrix} 0 & \cdots & 0 \\ \vdots & & \vdots \\ 0 & \cdots & 0 \end{bmatrix}$$

\mathbf{X} (X_1, \dots, X_n) is (are) the observation(s),
 \mathbf{A} an unknown matrix we want to determine,
 \mathbf{F} (F_1, \dots, F_n) the unobservable common factors (**factor scores**), that we (perhaps) want to determine (aka **latent variables**), and
 \mathbf{G} the unobservable unique factors

The factors are uncorrelated

Assumptions

The unique factors are uncorrelated

F and G are uncorrelated

The data has variance 1, i.e., the data is normalised / we use the correlation matrix

The Factor Model

$$[X_1 \quad \cdots \quad X_n] = A[F_1 \quad \cdots \quad F_n] + [G_1 \quad \cdots \quad G_n]$$

1) Determine A

principal factor solution version 1 is

$$A = [p_1, \dots, p_m] \begin{bmatrix} \sqrt{\lambda_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sqrt{\lambda_m} \end{bmatrix}$$

with $\lambda_1, \dots, \lambda_m$ the m largest eigenvalues for R , and p_1, \dots, p_m the corresponding eigenvectors

2) Rotate A

Principle factor solution for A is not unique.
For Q orthonormal, i.e. $QQ^T = I$ (Q is a rotation matrix), AQ is also a solution

$$(AQ)(AQ)^T = AQQ^T A^T = AA^T$$

3) Estimate F

$$E(F|X = x) = \mu_F + A^T R^{-1}(x - \mu_X) = A^T R^{-1}x$$

X (X_1, \dots, X_n) is (are) the standardized observation(s),

R is the variance matrix (correlation matrix) of **X**,

A a parametrized unknown matrix that we want to estimate,

F (F_1, \dots, F_n) the unobservable common factors (or **latent variables**),

G the unobservable unique factors

PCA is generally used to uncover structure, and reduce the number of variables

Factor Analysis estimates a **latent** model

PCA is just one way to estimate the **factor loadings A**; another option is e.g. maximum likelihood

In **Factor Analysis** we have a direct interpretations of **A**, e.g. communalities

Consequences of the model assumptions I

$$V(\mathbf{X}) = \mathbf{R} = V(\mathbf{A}\mathbf{F} + \mathbf{G}) = \mathbf{A}\mathbf{A}^T + \mathbf{\Delta}$$

$$V(X_i) = a_{i1}^2 + \dots + a_{im}^2 + \delta_i = h_i^2 + \delta_i = 1$$

$$\text{Cov}(\mathbf{X}, \mathbf{F}) = \text{Cov}(\mathbf{A}\mathbf{F} + \mathbf{G}, \mathbf{F}) = \mathbf{A}$$

$$\text{Cov}(X_i, F_j) = \text{Corr}(X_i, F_j) = a_{ij}$$

$$V \begin{bmatrix} \mathbf{X} \\ \mathbf{F} \end{bmatrix} = \begin{bmatrix} \mathbf{R} & \mathbf{A} \\ \mathbf{A}^T & \mathbf{I} \end{bmatrix}$$

$$V(\mathbf{X}|\mathbf{F}) = \mathbf{R} - \mathbf{A}\mathbf{A}^T = \mathbf{\Delta}$$

$$V \begin{bmatrix} X_i \\ \mathbf{F} \end{bmatrix} = \begin{bmatrix} 1 & [a_{i1} \ \dots \ a_{im}] \\ \begin{bmatrix} a_{i1} \\ \vdots \\ a_{im} \end{bmatrix} & \mathbf{I} \end{bmatrix}$$

$$V(X_i|\mathbf{F}) = 1 - [a_{i1} \ \dots \ a_{im}]\mathbf{I}^{-1} \begin{bmatrix} a_{i1} \\ \vdots \\ a_{im} \end{bmatrix} =$$

$$1 - (a_{i1}^2 + \dots + a_{im}^2) = \delta_i$$

$$V(X_i) - V(X_i|\mathbf{F}) = a_{i1}^2 + \dots + a_{im}^2 = h_i^2$$

h_i^2 is the i^{th} **communality**, the fraction of the variation in X_i that is explained by the common factors \mathbf{F} .

The **factor loading** a_{ij} is the correlation between the i^{th} variable and the j^{th} factor.

Remember that

$$\begin{aligned} E(X_1|X_2 = x_2) &= \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2) \\ V(X_1|X_2 = x_2) &= \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21} \end{aligned}$$

Consequences of the model assumptions II

$$V(X_i|F_j) = 1 - a_{ij}^2$$

$$V(X_1|F_j) + \dots + V(X_k|F_j) = k - (a_{1j}^2 + \dots + a_{kj}^2)$$

$$\Sigma V(X_i) - \{V(X_1|F_j) + \dots + V(X_k|F_j)\}$$

$$= a_{1j}^2 + \dots + a_{kj}^2$$

The part of the total variation explained by the j th factor

$$V \begin{bmatrix} F \\ X \end{bmatrix} = \begin{bmatrix} I & A^T \\ A & R \end{bmatrix}$$

$$E(F|X = x) = \mu_F + A^T R^{-1}(x - \mu_X) = A^T R^{-1}x$$

The estimated F -value (factor score) for known X -value

Again, remember that

$$E(X_1|X_2 = x_2) = \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2)$$

$$V(X_1|X_2 = x_2) = \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}$$

Inversion of k by k R can be replaced by inversion of an m by m matrix, see text book p. 413

The Principal Factor Solution version 1

Let

$$\mathbf{X} = \begin{bmatrix} X_1 \\ \vdots \\ X_k \end{bmatrix} \text{ with } V(\mathbf{X}) = \mathbf{R} = \begin{bmatrix} 1 & \cdots & \rho_{1k} \\ \vdots & \ddots & \vdots \\ \rho_{k1} & \cdots & 1 \end{bmatrix}, \quad \rho_{ij} = \rho_{ji}$$

Let the eigenvalues of $\mathbf{\Sigma} = \mathbf{R}$ be $\lambda_1 \geq \cdots \geq \lambda_k$ and the corresponding eigenvectors $\mathbf{p}_1, \cdots, \mathbf{p}_k$. Let $m \leq k$ and define

$$\mathbf{P}^{(m)} = [\mathbf{p}_1, \cdots, \mathbf{p}_m]$$
$$\mathbf{\Lambda}^{(m)} = \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_m \end{bmatrix}$$

Then the **principal factor solution version 1** is

$$\mathbf{A} = [\mathbf{p}_1, \cdots, \mathbf{p}_m] \begin{bmatrix} \sqrt{\lambda_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sqrt{\lambda_m} \end{bmatrix}$$

The Principal Factor Solution version 1

Let

$$\mathbf{X} = \begin{bmatrix} X_1 \\ \vdots \\ X_k \end{bmatrix} \text{ with } V(\mathbf{X}) = \mathbf{R} = \begin{bmatrix} 1 & \cdots & \rho_{1k} \\ \vdots & \ddots & \vdots \\ \rho_{k1} & \cdots & 1 \end{bmatrix}, \quad \rho_{ij} = \rho_{ji}$$

Let the eigenvalues of $\mathbf{\Sigma} = \mathbf{R}$ be $\lambda_1 \geq \cdots \geq \lambda_k$ and the corresponding eigenvectors $\mathbf{p}_1, \cdots, \mathbf{p}_k$. Let $m \leq k$ and define

$$\mathbf{P}^{(m)} = [\mathbf{p}_1, \cdots, \mathbf{p}_m]$$
$$\mathbf{\Lambda}^{(m)} = \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_m \end{bmatrix}$$

Then the **principal factor solution version 1** is

$$\mathbf{A} = [\mathbf{p}_1, \cdots, \mathbf{p}_m] \begin{bmatrix} \sqrt{\lambda_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sqrt{\lambda_m} \end{bmatrix}$$

Remember from PCA:

$$\mathbf{R} = \mathbf{P}\mathbf{\Lambda}\mathbf{P}^T = \mathbf{P}\mathbf{\Lambda}^{1/2}\mathbf{\Lambda}^{1/2}\mathbf{P}^T = \mathbf{P}\mathbf{\Lambda}^{1/2}(\mathbf{P}\mathbf{\Lambda}^{1/2})^T = \mathbf{A}\mathbf{A}^T$$

However, in general in the factor model,

$$V(\mathbf{X}) = \mathbf{R} = V(\mathbf{A}\mathbf{F} + \mathbf{G}) = \mathbf{A}\mathbf{A}^T + \mathbf{\Delta}$$

Version 1 of the principle factor model **disregards contribution from the independent factor \mathbf{G} .**

Consequences of the model assumptions I

$$V(X) = R = V(AF + G) = AA^T + \Delta$$

$$V(X_i) = a_{i1}^2 + \dots + a_{im}^2 + \delta_i = h_i^2 + \delta_i = 1$$

$$\text{Cov}(X, F) = \text{Cov}(AF + G, F) = A$$

$$\text{Cov}(X_i, F_j) = \text{Corr}(X_i, F_j) = a_{ij}$$

$$V \begin{bmatrix} X \\ G \end{bmatrix} = \begin{bmatrix} R & \Delta \\ \Delta & \Delta \end{bmatrix}$$

$$V(X|G) = R - \Delta\Delta^{-1}\Delta = R - \Delta = AA^T$$

Model assumption:

For given G , h_i^2 is the level of variation of X_i .

We do not know h_i^2 . But when we condition on G , all variation originates from F , and the diagonal elements of the variance matrix are less than 1.

To take effects of G into account when estimating, it is thus custom to replace the diagonal elements of R with lower values. The choice we make is the total level of explainability in the system, ie. the (squared) multiple correlation coefficient.

Remember that

$$\begin{aligned} E(X_1|X_2 = x_2) &= \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2) \\ V(X_1|X_2 = x_2) &= \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21} \end{aligned}$$

The Principal Factor Solution version 2

Let

$$\mathbf{X} = \begin{bmatrix} X_1 \\ \vdots \\ X_k \end{bmatrix} \text{ with } V(\mathbf{X}) = \mathbf{R} = \begin{bmatrix} 1 & \cdots & \rho_{1k} \\ \vdots & \ddots & \vdots \\ \rho_{k1} & \cdots & 1 \end{bmatrix}, \quad \rho_{ij} = \rho_{ji}$$

Define the matrix \mathbf{V} by

$$\mathbf{V} = \begin{bmatrix} \rho_{1|2,\dots,k}^2 & \cdots & \rho_{1k} \\ \vdots & \ddots & \vdots \\ \rho_{k1} & \cdots & \rho_{k|1,\dots,k-1}^2 \end{bmatrix}$$

Let the eigenvalues of \mathbf{V} be $\lambda_1 \geq \cdots \geq \lambda_k$ and the corresponding eigenvectors $\mathbf{p}_1, \dots, \mathbf{p}_k$. Let $m \leq k$ and define

$$\mathbf{P}^{(m)} = [\mathbf{p}_1, \dots, \mathbf{p}_m]$$
$$\mathbf{\Lambda}^{(m)} = \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_m \end{bmatrix}$$

Then the **principal factor solution version 2** is

$$\mathbf{A} = [\mathbf{p}_1, \dots, \mathbf{p}_m] \begin{bmatrix} \sqrt{\lambda_1} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \sqrt{\lambda_m} \end{bmatrix}$$

The `principal` Function

`principal {psych}`

R Documentation

Principal components analysis (PCA)

Description

Does an eigen value decomposition and returns eigen values, loadings, and degree of fit for a specified number of components. Basically it is just doing a principal components analysis (PCA) for `n` principal components of either a correlation or covariance matrix. Can show the residual correlations as well. The quality of reduction in the squared correlations is reported by comparing residual correlations to original correlations. Unlike `princomp`, this returns a subset of just the best `nfactors`. The eigen vectors are rescaled by the sqrt of the eigen values to produce the component loadings more typical in factor analysis.

Factor analysis coding of the Heptathlon data

```

- Disregarding sign changes, these vectors are identical. No smoothing.

Factor loadings

On the ML estimation method

Pro:

- Asymptotically Unbiased;
- Model founded – distributions of related statistics may be derived from that;
- Minimized variation subject to model adherence;
- Solution is scale-independent (see page [417-18](#)).
- Makes the factor structure testable.

Con:

- No closed form expression of the estimators $\hat{A}, \hat{\Delta}$ exists; solutions to the likelihood equation

$$\hat{A} = (\hat{A}\hat{A}^T + \hat{\Delta})R^{-1}\hat{A}$$

where the solution does not have an analytic expression.

- Subject to model assumptions on distributions (normality) that may fail.

Testing the factor structure

Test statistic:

$$Z = \left(n - 1 - \frac{1}{6}(2k + 5) - \frac{2}{3}m \right) \log \left(\frac{|\hat{A}\hat{A}^T + \hat{\Delta}|}{|R|} \right)$$

Which asymptotically follows a $\chi^2 \left(\frac{1}{2}((k - m)^2 - k - m) \right)$ distribution.

n: # observations

k: # variables

m: # factors

Testing the factor structure – 3 factors

$$Z = \left(n - 1 - \frac{1}{6}(2k + 5) - \frac{2}{3}m \right) \log \left(\frac{|\hat{A}\hat{A}^T + \hat{\Delta}|}{|R|} \right)$$

R:

```
temp<- fa(R,nfactors = 3,rotate = "varimax",smc=T,n.obs=25,scores="regression",fm="ml")
```

```
A<-temp$loadings[,]
```

```
n<-25
```

```
k<-7
```

```
m<-3

Borderline significant

Note: temp\$STATISTIC=7.81 should essentially be the same as the above, except for number representation. Gives p=0.0501, borderline insignificant.

Testing the factor structure – 3 factors

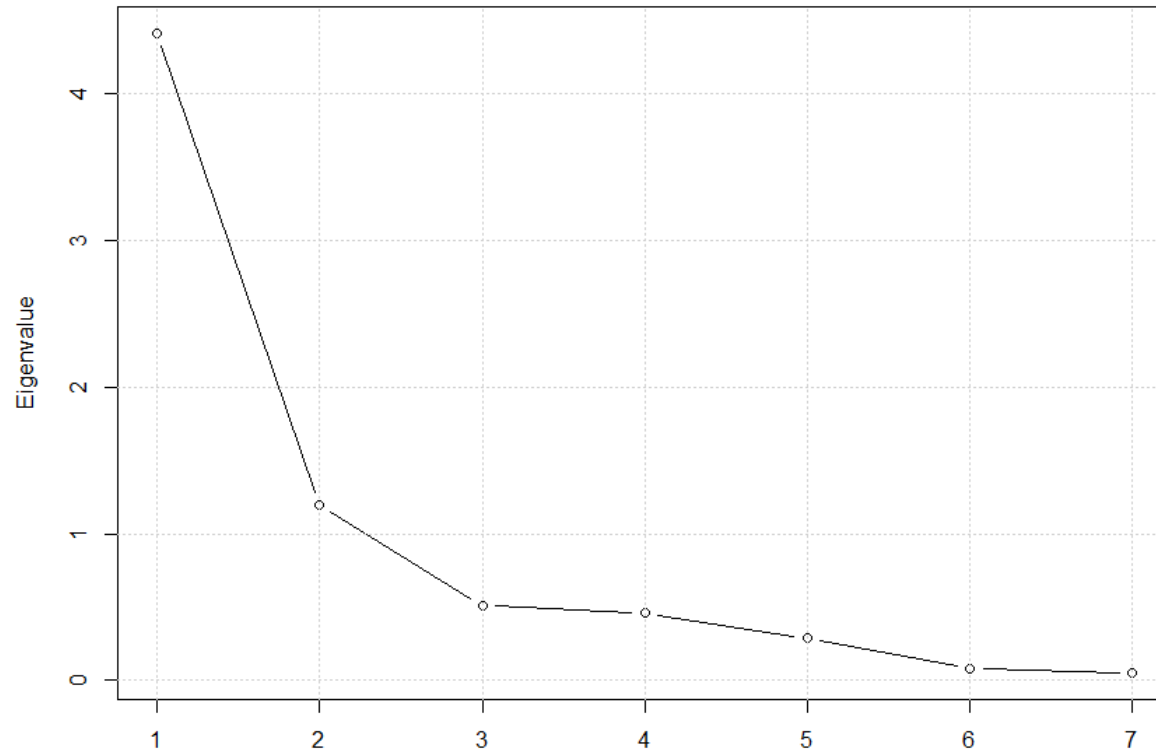

What to do?

Increase the number of factors?

- There is a catch – the asymptotic distribution is $\chi^2 \left(\frac{1}{2} ((k - m)^2 - k - m) \right)$.
- $\frac{1}{2} ((7 - 3)^2 - 7 - 3) = 3,$
- $\frac{1}{2} ((7 - 4)^2 - 7 - 4) = -1$
- **Describing 7 variables from 4 factors (and independent factors) is not testable;** the model is overparametrized.
- Parameters under the model with free ranging correlation: $k(k - 1)/2$.
- Parameters under the factor model: $mk - m(m - 1)/2$.
- Difference: $\frac{1}{2} ((k - m)^2 - k - m)$.
- **More parameters under the factor model with 4 factors.**

Testing the factor structure – 3 factors

- Bordeline case – and:

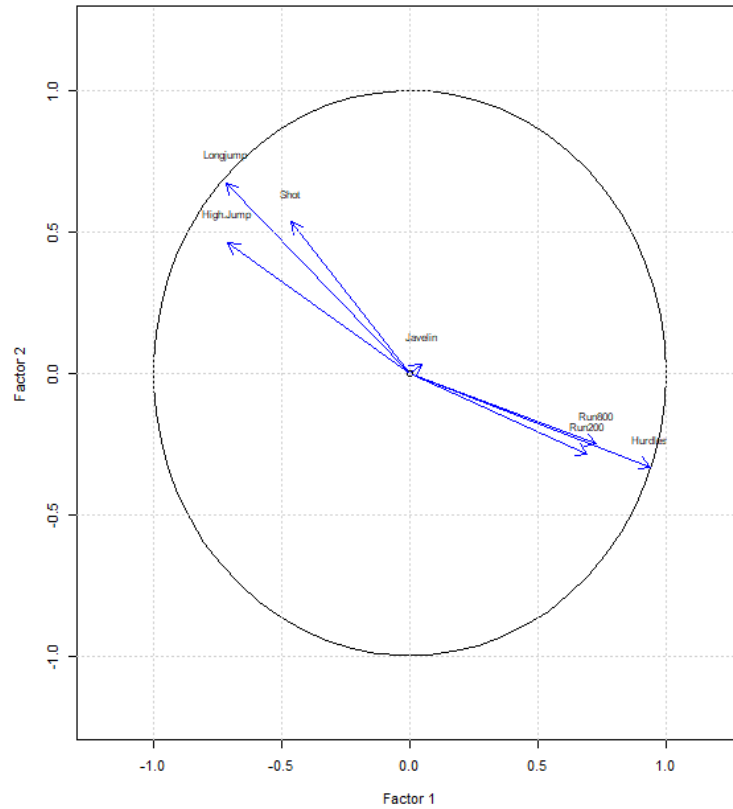

- Suggests 2-3 eigenvectors describing R .

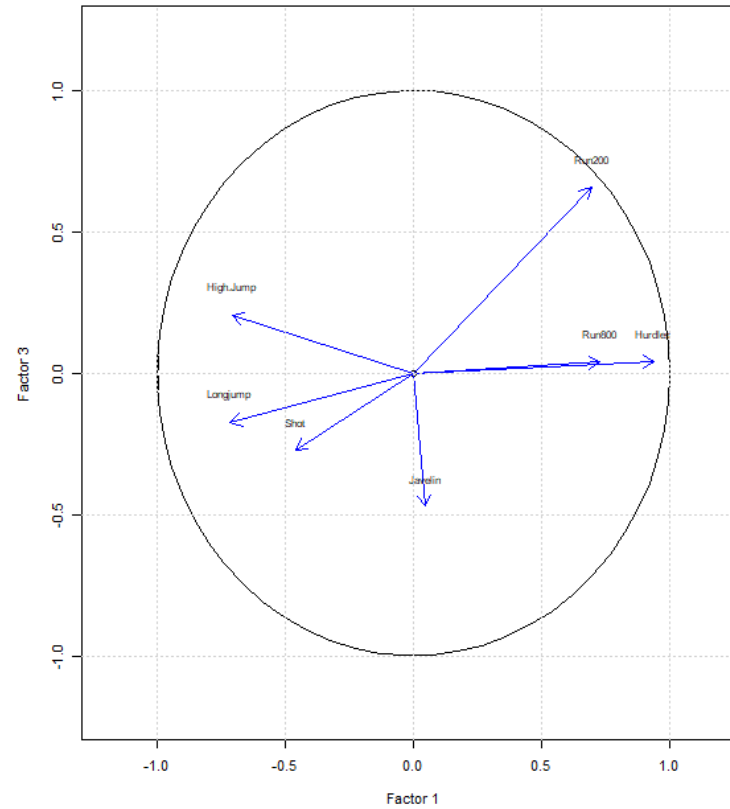

Factor loadings

rotated ml estimation with smc

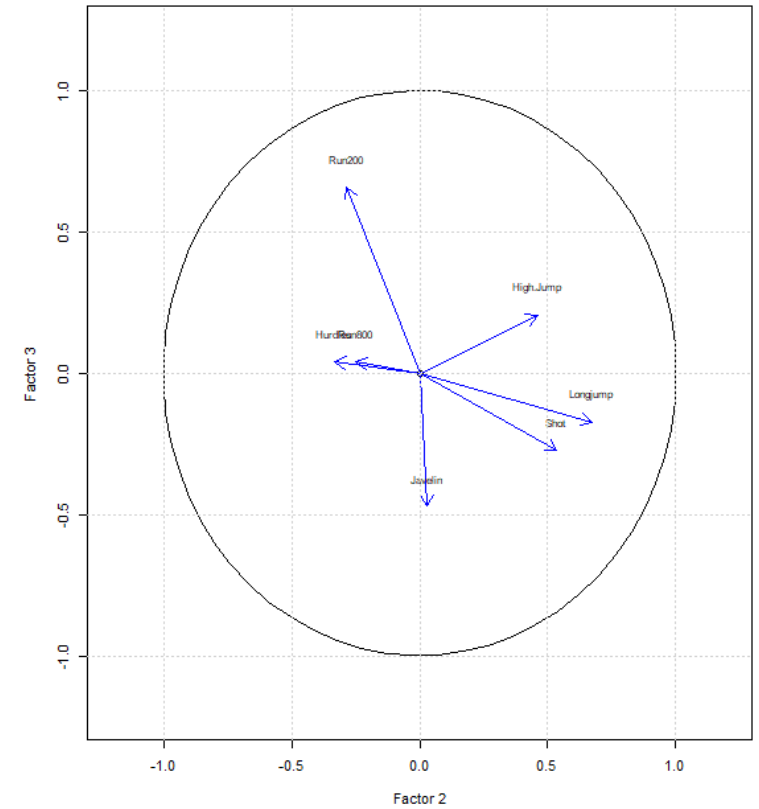

Loadingsplot, Factors 1 and 2

Loadingsplot, Factors 1 and 3

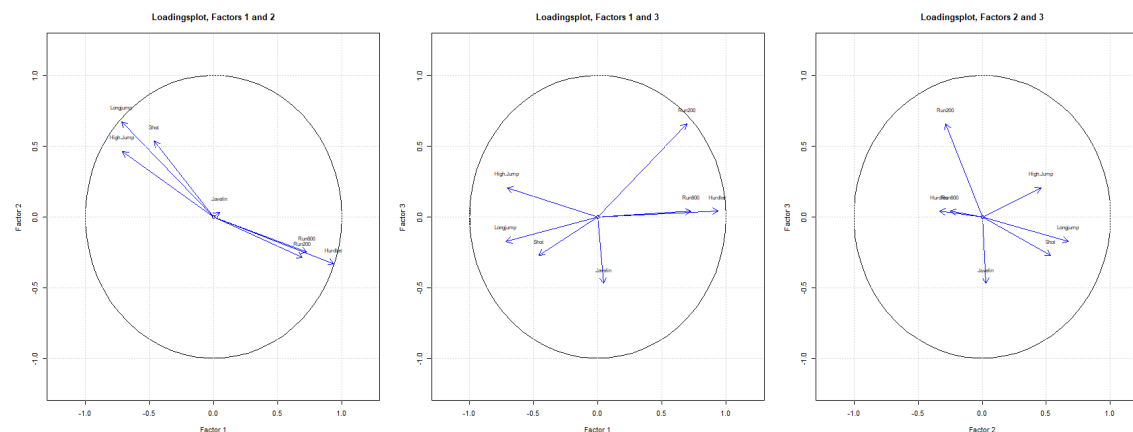

Loadingsplot, Factors 2 and 3

Factor loadings

rotated ml estimation with smc

- Factor 1: Technical running vs. technical jump/shot;
- Factor 2: Powerful jump/shot vs. running;
- Factor 3: Sprint vs. Power/javelin.

Testing the factor structure – 3 factors

- Estimating the unknown factor values
- $E(F|X = x) = A^T R^{-1} x$

- Joyner-Kersee excels in both technical and powerful jumps/shot vs. running; she excels in power over sprint;
a very strong and skilled athlete.
- Launa excels in running over jumps/shot, but not sprint;
a strong and technically skilled runner;
- Kytola excels in running and power/jarvelin;
Kytola is Finnish, their national sport is the Jarvelin.

Heptathlon data –uniqueness factors

```
barplot(temp$uniquenesses,col=rainbow(7),ylim=c(0,1))  
box()
```

- Hurdles, 200 Meter Run and Long Jump are essentially completely explained from the factors.
- High Jump, Shot Put, Jarvelin Throw and 800 Meter Run have a larger degree of unique variation, in particular Jarvelin Throw.
- High Jump, Shot Put and Jarvelin Throw are all disciplines with a technical element. 800 Meter Run has a tactical element where conservation of power is a main asset.
- Hurdles, 200 Meter Run and Long Jump, while also for Hurdles and Long Jump containing a technical element, are discipline where direct exposure of strength is a key element.

Canonical Correlation

y, x : **Correlation**. Data are divided into two variables x and y .

$y, x_1 + \dots + x_p$: **Multiple correlation**.

Maximal correlation between y and a linear combination of x . Data are divided into one variable y , and a set of variables x_1, \dots, x_p .

$y_1 + y_2 + \dots + y_p, x_1 + x_2 + \dots + x_q$: **Canonical correlation**.

Maximal correlation between a linear combination of y and a linear combination of x ; data are divided into sets of variables x and y .

The most "multivariate" of the correlation forms that we are going to study.

Canonical correlation identifies and quantifies the relations between *two sets of variables*.

Canonical correlation analysis identifies the *linear combination* of one set that is *maximally correlated* to a linear combination of the other set.

Canonical Correlation

- Suppose that we want to investigate the relationship between two parts $Y = (Y_1, \dots, Y_p)$ and $X = (X_1, \dots, X_q)$ of a dataset;
- We assume that a 2nd order moment representation of the simultaneous distribution of $Z = (Y^T, X^T)^T$ is

$$Z = A = \begin{bmatrix} Y \\ X \end{bmatrix}, \mu = E[Z] = \begin{bmatrix} \mu_y \\ \mu_x \end{bmatrix}, V[Z] = \Sigma = \begin{bmatrix} \Sigma_{yy} & \Sigma_{yx} \\ \Sigma_{xy} & \Sigma_{xx} \end{bmatrix},$$

Where we assume that Σ_{yy}, Σ_{xx} both are regular so that the inverse exists;

- If not, one of the variables may be expressed as a linear relation from the others (essentially Exercise E1); reduce the number of variables studied, or work with generalized inverse matrices in the formulas to follow.

Canonical Correlation

Definition 6.11

Consider Z as above. Then the first *pair of canonical variables* is the pair of linear combinations

$$V_1 = a_1^T Y \text{ and } W_1 = b_1^T X$$

each having variance 1 that maximize the correlation $\rho(a^T Y, b^T X)$ for all (a, b) . The maximum correlation ρ_1 is the *first canonical correlation*. For $r \leq p$ we define the *r'th pair of canonical variables* as the pair of linear combinations

$$V_r = a_r^T Y \text{ and } W_r = b_r^T X ,$$

which each has the variance 1, which are uncorrelated with the previous $r - 1$ pairs of canonical variables, and which maximizes the correlation $\rho(a^T Y, b^T X)$ under those constraints. The maximum correlation ρ_r is the *r'th canonical correlation*.

Canonical Correlation

Lets us look at the covariance between a linear combination \mathbf{a} of Y and a linear combination \mathbf{b} of X:

$$\text{Cov}(\mathbf{a}^T Y, \mathbf{b}^T X) = \mathbf{a}^T \text{cov}(Y, X) \mathbf{b} = \mathbf{a}^T \Sigma_{yx} \mathbf{b}$$

The correlation is

$$\text{Cor}(\mathbf{a}^T Y, \mathbf{b}^T X) = \frac{\mathbf{a}^T \Sigma_{yx} \mathbf{b}}{\sqrt{\mathbf{a}^T \Sigma_{yy} \mathbf{a} \mathbf{b}^T \Sigma_{xx} \mathbf{b}}}$$

We want to find linear combinations so that the correlation between the linear combinations is maximal; ie. Solve the maximization problem

$$\max_{\mathbf{a}, \mathbf{b}} \mathbf{a}^T \Sigma_{yx} \mathbf{b}$$

$$\text{subject to } \mathbf{a}^T \Sigma_{yy} \mathbf{a} = 1, \quad \mathbf{b}^T \Sigma_{xx} \mathbf{b} = 1$$

Canonical Correlation

Technique: Lagrange multipliers: The problem transforms into the maximization problem

$$\max_{\mathbf{a}, \mathbf{b}} \left\{ \mathbf{a}^T \Sigma_{yx} \mathbf{b} - \frac{\lambda_1}{2} (\mathbf{a}^T \Sigma_{yy} \mathbf{a} - 1) - \frac{\lambda_2}{2} (\mathbf{b}^T \Sigma_{xx} \mathbf{b} - 1) \right\} \quad (1)$$

Differentiating (1) with respect to \mathbf{a}, \mathbf{b} , and putting equal to 0 gives

$$\begin{aligned} \Sigma_{yx} \mathbf{b} - \lambda_1 \Sigma_{yy} \mathbf{a} &= 0 \\ \mathbf{a}^T \Sigma_{yx} - \lambda_2 \Sigma_{xx} \mathbf{b} &= 0 \end{aligned} \quad (2)$$

ie.

$$\begin{aligned} \mathbf{a} &= \frac{1}{\lambda_1} \Sigma_{yy}^{-1} \Sigma_{yx} \mathbf{b} \\ \mathbf{b} &= \frac{1}{\lambda_2} \Sigma_{xx}^{-1} \Sigma_{xy} \mathbf{a} \end{aligned} \quad (3)$$

Inserting bottom expression of (3) into top expression of (2) and vice versa gives

$$\begin{aligned} (\Sigma_{yx} \Sigma_{xx}^{-1} \Sigma_{xy} - \lambda_1 \lambda_2 \Sigma_{yy}) \mathbf{a} &= 0 \\ (\Sigma_{xy} \Sigma_{yy}^{-1} \Sigma_{yx} - \lambda_1 \lambda_2 \Sigma_{xx}) \mathbf{b} &= 0 \end{aligned} \quad (4)$$

Or

$$\begin{aligned} (\Sigma_{yy}^{-1} \Sigma_{yx} \Sigma_{xx}^{-1} \Sigma_{xy} - \lambda_1 \lambda_2) \mathbf{a} &= 0 \\ (\Sigma_{xx}^{-1} \Sigma_{xy} \Sigma_{yy}^{-1} \Sigma_{yx} - \lambda_1 \lambda_2) \mathbf{b} &= 0 \end{aligned} \quad (5)$$

Canonical Correlation

$$\begin{aligned}(\Sigma_{yy}^{-1}\Sigma_{yx}\Sigma_{xx}^{-1}\Sigma_{xy} - \lambda_1\lambda_2)\mathbf{a} &= 0 \\(\Sigma_{xx}^{-1}\Sigma_{xy}\Sigma_{yy}^{-1}\Sigma_{yx} - \lambda_1\lambda_2)\mathbf{b} &= 0\end{aligned}\tag{5}$$

Take

$$\begin{aligned}E_1 &= \Sigma_{yy}^{-1}\Sigma_{yx}\Sigma_{xx}^{-1}\Sigma_{xy} \\E_2 &= \Sigma_{xx}^{-1}\Sigma_{xy}\Sigma_{yy}^{-1}\Sigma_{yx}\end{aligned}$$

Note that E_1 is a $p \times p$ matrix, while E_2 is a $q \times q$ matrix.

Equation (5) then reads that \mathbf{a}, \mathbf{b} are **eigenvectors** for respectively E_1, E_2 , with the **same** eigenvalue $\varrho^2 = \lambda_1\lambda_2$. This is optimized if ϱ^2 is taken as the largest eigenvalue for E_1 (and thus for E_2).

Obviously, this procedure may be iterated to find the maximal correlations perpendicular to \mathbf{a}, \mathbf{b} , respectively, as the remaining eigenvectors of E_1, E_2 .

Canonical Correlation

||| Theorem 6.12

Let the situation be given in the above mentioned definition and let $D(Z) = \Sigma$ be partitioned analogously

$$\Sigma = \begin{bmatrix} \Sigma_{yy} & \Sigma_{yx} \\ \Sigma_{xy} & \Sigma_{xx} \end{bmatrix}$$

Then the r' th canonical correlation is equal to the r' th largest root ϱ_r of

$$\det \begin{bmatrix} -\rho \Sigma_{yy} & \Sigma_{yx} \\ \Sigma_{xy} & -\rho \Sigma_{xx} \end{bmatrix} = 0$$

and the coefficients in the r' th pair of canonical variables satisfies

$$\begin{aligned} \text{(i)} \quad & \begin{bmatrix} -\varrho_r \Sigma_{yy} & \Sigma_{yx} \\ \Sigma_{xy} & -\varrho_r \Sigma_{xx} \end{bmatrix} \begin{bmatrix} a_r \\ b_r \end{bmatrix} = 0 \\ \text{(ii)} \quad & a_r^T \Sigma_{yy} a_r = 1 \\ \text{(iii)} \quad & b_r^T \Sigma_{xx} b_r = 1 \end{aligned}$$

||| Theorem 6.13

Let the situation be as in the previous theorem. Then we have

$$(\Sigma_{yx} \Sigma_{xx}^{-1} \Sigma_{xy} - \varrho_r^2 \Sigma_{yy}) a_r = 0$$

$$\det (\Sigma_{yx} \Sigma_{xx}^{-1} \Sigma_{xy} - \varrho_r^2 \Sigma_{yy}) = 0$$

respectively

$$(\Sigma_{xy} \Sigma_{yy}^{-1} \Sigma_{yx} - \varrho_r^2 \Sigma_{xx}) b_r = 0$$

$$\det (\Sigma_{xy} \Sigma_{yy}^{-1} \Sigma_{yx} - \varrho_r^2 \Sigma_{xx}) = 0$$

- Note that Theorem 6.12 concerns ϱ , and Theorem 6.13 concerns ϱ^2 . Finding the solutions through E_1, E_2 thus means that the canonical correlation ϱ_r is obtained as the square root of the eigenvalue ϱ_r^2 .

Canonical Correlation

- Assume wlog that $p < q$, so that we may represent the correlation between Y and X through p pairs of eigenvectors \mathbf{a}, \mathbf{b} . Then there are at most p positive eigenvalues for E_1, E_2 . The eigenvectors a_1, \dots, a_p and b_1, \dots, b_p for respectively E_1, E_2 are called *the canonical vectors*, the linear combinations $A^T Y, B^T X$ the *canonical variables* for Y, X , respectively, while the square root of the eigenvalues ρ_1, \dots, ρ_p are called the *canonical correlations* between Y and X .

Canonical Correlation

- Take

$$\Delta_y = \begin{bmatrix} \sigma_{y_1}^{-1} & & \\ & \ddots & \\ & & \sigma_{y_p}^{-1} \end{bmatrix}, \Delta_x = \begin{bmatrix} \sigma_{x_1}^{-1} & & \\ & \ddots & \\ & & \sigma_{x_q}^{-1} \end{bmatrix} \Delta = \begin{bmatrix} \Delta_y & \\ & \Delta_x \end{bmatrix}$$

The the correlation matrix for Z is

$$R = \Delta \Sigma \Delta$$

Note that

$$V(\Delta_y Y) = \Delta_y \Sigma_{yy} \Delta_y = R_y, V(\Delta_x X) = \Delta_x \Sigma_{xx} \Delta_x$$

Canonical Correlation

- Take $A = (a_1; \dots; a_p)$, $B = (b_1; \dots; b_p)$ to be the canonical vectors $V = A^T Y$, $W = B^T X$ to be the canonical variables. Then

$$V \begin{bmatrix} Y \\ X \\ V \\ W \end{bmatrix} = \begin{bmatrix} R_{yy} & R_{yx} & R_{yv} & R_{yw} \\ R_{xy} & R_{xx} & R_{xv} & R_{xw} \\ R_{vy} & R_{vx} & I_p & R_{vw} \\ R_{wy} & R_{wx} & R_{wv} & I_p \end{bmatrix}$$

With

$$R_{vw} = R_{wv} = \begin{pmatrix} \varrho_1 & & \\ & \ddots & \\ & & \varrho_p \end{pmatrix}$$

The remaining 4 elements may be found from the definition of V and W :

$$\text{Cor}(Y, V) = \text{Cov}(\Delta_y Y, A^T Y) = \Delta_y \Sigma_{yy} A = R_{yy} \Delta_y^{-1} A$$

$$\text{Cor}(Y, W) = \text{Cov}(\Delta_y Y, B^T X) = \Delta_y \Sigma_{yx} B = R_{yx} \Delta_x^{-1} B$$

$$\text{Cor}(X, V) = \text{Cov}(\Delta_x X, A^T Y) = \Delta_x \Sigma_{xy} A = R_{xy} \Delta_y^{-1} A$$

$$\text{Cor}(X, W) = \text{Cov}(\Delta_x X, B^T X) = \Delta_x \Sigma_{xx} B = R_{xx} \Delta_x^{-1} B$$

Canonical Correlation

$$Cor(Y, V) = Cov(\Delta_y Y, A^T Y) = \Delta_y \Sigma_{yy} A = R_{yy} \Delta_y^{-1} A$$

$$Cor(Y, W) = Cov(\Delta_y Y, B^T X) = \Delta_y \Sigma_{yx} B = R_{yx} \Delta_x^{-1} B$$

$$Cor(X, V) = Cov(\Delta_x X, A^T Y) = \Delta_x \Sigma_{xy} A = R_{xy} \Delta_y^{-1} A$$

$$Cor(X, W) = Cov(\Delta_x X, B^T X) = \Delta_x \Sigma_{xx} B = R_{xx} \Delta_x^{-1} B$$

Note that the canonical vectors above enter through the standization

$$\Delta_y^{-1} A = \begin{pmatrix} \sigma_{y_1} & & \\ & \ddots & \\ & & \sigma_{y_p} \end{pmatrix} A, \quad \Delta_x^{-1} B = \begin{pmatrix} \sigma_{x_1} & & \\ & \ddots & \\ & & \sigma_{x_q} \end{pmatrix} B$$

This leads to that one often represent the canonical variables in the so-called *standardized form*:

$$V^* = (\Delta_y^{-1} A)^T Y = A^T \Delta_y^{-1} Y, \quad W^* = (\Delta_x^{-1} B)^T X = B^T \Delta_x^{-1} X$$

Testing that a canonical correlation is 0

- So far, we have not invoked distributional properties of the data apart from the 2nd order moment representation.
- We now make the further assumption that data follows a normal distribution. The distribution is completely specified by mean and variance.
- Simultaneous distribution of normalized $(a_p^T Y, b_p^T X)$, corresponding to the smallest canonical correlation:

$$N \left(\begin{pmatrix} a_p^T \mu_y \\ b_p^T \mu_x \end{pmatrix}, \begin{pmatrix} 1 & \rho_p \\ \rho_p & 1 \end{pmatrix} \right)$$

Testing that a canonical correlation is 0

$$N\left(\begin{pmatrix} a_p^T \mu_y \\ b_p^T \mu_x \end{pmatrix}, \begin{pmatrix} 1 & \varrho_p \\ \varrho_p & 1 \end{pmatrix}\right)$$

Testing

$$H_0: \varrho_p = 0 \quad vs. \quad H: \varrho_p > 0$$

thus conforms with testing that the variance matrix is diagonal.

Test statistic (Bartlett's test):

$$Q = -\left(n - \frac{p + q + 3}{2}\right) \log(1 - \varrho_p^2) \sim \chi_{q-p+1}^2$$

Note that if $p = q$, the degrees of freedom is 1. Because the canonical variables are independent, the tests may be carried out sequentially. The cc function derives simultaneous tests based on the Wilks distribution; see the following example.

The fewer the non-zero canonical correlations, the less and the simpler the dependencies between Y and X.

- We will get back to tests for covariance structure with the multivariate analysis of variance

Canonical correlation

Canonical correlation analysis has a reputation of being the most difficult multivariate technique to interpret. In many respects it is a well earned reputation! Certainly one has to know the variables involved very well to have any hope of extracting a convincing explanation. But in some circumstances (...), CCA does provide a useful description of the association between two sets of variables.

- Brian Everitt, 2005.

Example: Heads measurements data

- The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimeters.

```
frets<-read.csv2("Data/frets.csv")
```

```
head(frets)
```

	l1	b1	l2	b2
1	191	155	179	145
2	195	149	201	152
3	181	148	185	149
4	183	153	188	149
5	176	144	171	142
6	208	157	192	152

L1: The head length of the eldest son.

B1: The head breadth of the eldest son.

L2: The head length of the second son.

B2: The head breadth of the second son.

Example: Heads measurements data

Correlation structure:

```
frets2<-scale(frets,center=T,scale=T)
round(cov(frets2),digits=2)
      l1    b1    l2    b2
l1  1.00  0.73  0.71  0.70
b1  0.73  1.00  0.69  0.71
l2  0.71  0.69  1.00  0.84
b2  0.70  0.71  0.84  1.00
```

We want to study the correlation between the eldest and the second son:

$$Y = (l1, b1)^T, X = (l2, b2)^T$$

Example: Heads measurements data

Correlation structure:

```
brother1<-frets2[,1:2]
```

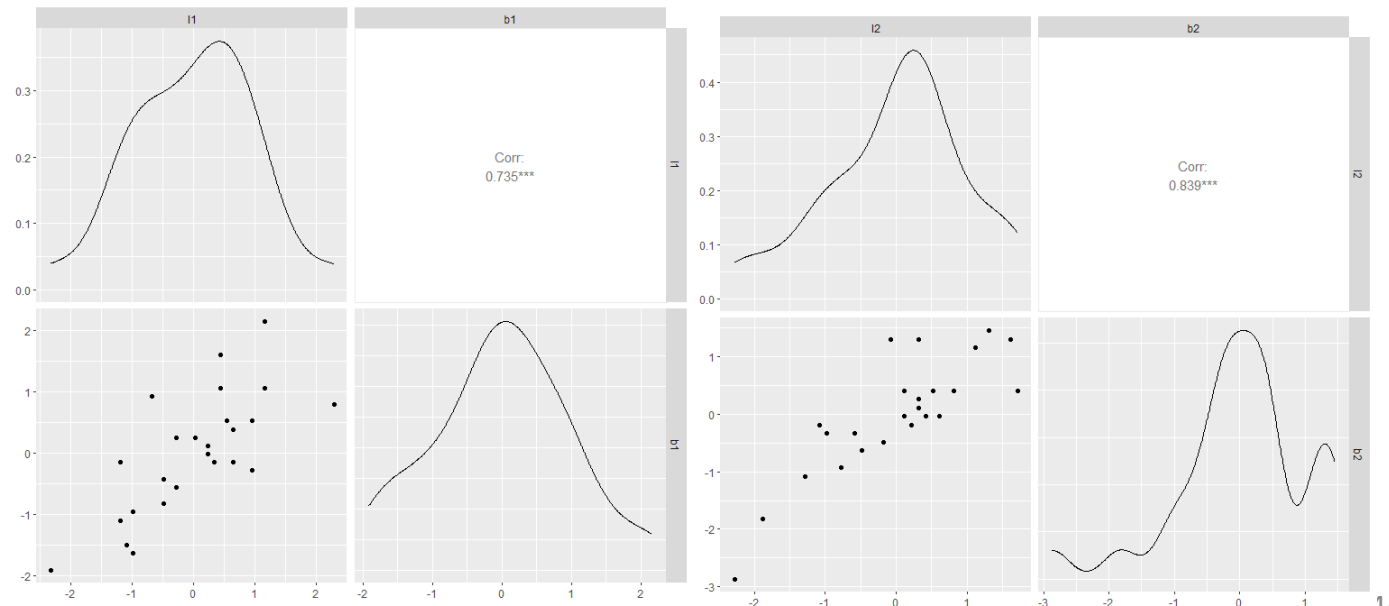

```
brother2<-frets2[,3:4]
```

```
ggpairs(brother1)
```

```
ggpairs(brother2)
```

```
round(cov(brother1,brother2),digits=2)
```

	l2	b2
l1	0.71	0.70
b1	0.69	0.71

Example: Heads measurements data

- Finding E_1, E_2 :

```
R11<-cor(brother1)
```

```
R22<-cor(brother2)
```

```
R12<-cor(brother1,brother2)
```

```
R21<-t(R12)
```

```
E1<-solve(R11)%*%R12*solve(R22)%*%R21
```

```
E2<-solve(R22)%*%R21*solve(R11)%*%R12
```

- Finding the canonical correlations:

```
(my.cor<-sqrt(eigen(E1)$values))
```

```
[1] 0.7885079 0.0537397
```

Example: Heads measurements data

```
E1<-solve(R11)%*%R12%%solve(R22)%*%R21
E2<-solve(R22)%*%R21%%solve(R11)%*%R12
```

- Finding A, B :

```
A<-eigen(E1)$vectors
B<-eigen(E2)$vectors
```

- Vectors are unit vectors; Standardizing the length (and sign):

```
A<-A%%solve(diag(sqrt(diag(t(A)%*%R11)%*%A))))
B<-B%%solve(diag(sqrt(diag(t(B)%*%R22)%*%B))))
B[,1]<--B[,1]
```

- Checking:

```
round(t(A)%*%R11)%*%A,digits=6)
      [,1] [,2]
[1,]      1      0
[2,]      0      1
round(t(B)%*%R22)%*%B,digits=6)
      [,1] [,2]
[1,]      1      0
[2,]      0      1
>

Heads measurements data: Summing up

$$\begin{aligned} T &= Y^T Y = (n-1) \hat{\Sigma}_{yy} \\ H &= Y^T X (X^T X)^{-1} X^T Y = (n-1) \hat{\Sigma}_{yx} \hat{\Sigma}_{xx}^{-1} \hat{\Sigma}_{xy} \\ E &= T - H = (n-1) (\hat{\Sigma}_{yy} - \hat{\Sigma}_{yx} \hat{\Sigma}_{xx}^{-1} \hat{\Sigma}_{xy}) \end{aligned}$$

We see that T corresponds to the total variation and E to the residual variation after having predicted Y by means of X .

||| Theorem 6.16

Testing whether the canonical correlations are zero is equivalent to test whether the eigenvalues of $E^{-1}H$ are zero.

- Summing up from the cc function, using the test form above (F approximation rather than Chisquare:

	CanCor	Squared.CanCor	eigenvalues	InvEH	proportion	cumulative	id
1	0.7885079	0.621744734	1.64371733	0.998241044	0.998241	Wilks	
2	0.0537397	0.002887956	0.00289632	0.001758956	1.000000	Wilks	

	stat	approx	df1	df2	p.value
1	0.3771629	6.59719349	4	42	0.0003256458
2	0.9971120	0.06371905	1	22	0.8030550074

- One canonical coefficient is sufficient; girth correlates between brothers but there is no evidence that shape does.
